Roll-formed beams are one of the most common types of beams used in racking systems. These beams are created by feeding a flat metal sheet through a series of rollers that gradually shape the metal into a beam-like form. Their hollow, rectangular or square cross-section provides high strength while reducing weight, making them perfect for long spans and heavy. PRESTRES is a prestressed concrete beam design and analysis program for simply supported beams. The program has been tailored for highway bridge girders; however, with modifications, it can be used to design piers and buildings.

AASHTO Load Distribution

Section 3.28 of the AASHTO Standard Specifications defines the methods for calculating the live load distribution factor for a prestressed concrete spread box beam superstructure. Equation

AASHTO Load Distribution

I designed a bridge with prestressed concrete box beams and composite concrete deck about one year ago. We used Staadpro 2005 to model the deck using elements and the graphic

Section 9: Pretensioned Concrete Box Beams

Distribute the weight of one railing to no more than three beams. Use section properties given on the Prestressed Box Beams standard drawings. For the composite section, use gross section properties.

Prestressed Concrete Box Beams Distribution Factor Spreadsheet

Since the exterior beam can be of a different width than the interior beam, the Live Load Distribution Factors need to be calculated for an interior beam that has the same width as the exterior beam.
