

How many megabytes can an optical module transmit

Overview

Optical modules for LAN networks can transmit data at rates of up to 10 Gb/s, while those for WAN networks can transmit data over distances of up to 80 km. Modern optical modules convert electrical data to optical data to overcome losses associated with electrical transmission. With each generation, they deliver higher data rates, such as 100 Gbps, 400 Gbps, and soon 800 Gbps. Understanding their key parameters isn't just technical jargon – it's critical for ensuring compatibility, performance, and reliability in your data center. The data capacity of a fiber cable refers to how much information it can transmit per second — usually measured in gigabits per second (Gbps) or terabits per second (Tbps). In theory, optical fibers can handle terabits of data every second, and in experimental settings, this number has skyrocketed. The optical module serves as a crucial component in optical fiber communication systems, operating at the physical layer, which is the lowest layer in the OSI model. Optical modules typically have an electrical interface on the side that connects to the inside of the system and an optical interface on the side that connects to the outside. Optical modules can be divided into: 100Mbps optical modules: Usually labeled as 155M, 100Base, FE, etc. ► 1Gbps optical modules: Common representations include 1G, 1.
