

## How to calculate the maximum load of a distribution box

### Overview

The basic principle is straightforward: assess the load on each circuit, then apply diversity factors to arrive at a realistic total. **Peak Load:** The maximum load consumed or produced by a group of units in a stated period of time. **Maximum Demand:** The greatest of all demands that have occurred during a specified period of time. The demand factor is the ratio of the maximum demand on a system to the total connected load of the system. This factor must be applied to each individual load, with particular attention to electric motors, which are very rarely operated at full load. Demand factors for buildings typically range. Before we dive into calculations, let's get familiar with a few essentials: 1. Your Project's Total Power Demand This isn't just adding up wattages randomly.
