

Laser Diode Waveform Modulation

Overview

Modulating the output power of a laser diode can happen in two ways: by changing the signal input/driving current^{1,2} or by alternating the continuous wave output after the light is generated. ² In laser modulation, the current or voltage varies with time to modulate the output signal from the laser. Laser modulation is a critical facet of laser technology, allowing for controlled variations in key parameters such as intensity, frequency, or phase. Such control opens the door to a broad range of scientific and commercial applications. The functional diagram of the LD100 laser is shown below. However, it internally is also modulate possible the output of to a semiconductor laser controlling by either. We present a current modulation technique for diode laser systems, which is specifically designed for high-bandwidth laser frequency stabilization and wideband frequency modulation with a flat transfer function.
