

New type of optical modulator

Overview

Kyushu University researchers have successfully developed an ultra-high-speed optical modulator that can operate at more than 10 times the speed of current devices. Optical modulators are devices that modify the properties of light, such as its amplitude, phase, frequency, or polarization, in response to an external signal. Over the decades, scientists have researched and developed silicon photonic modulators with wide-ranging applications, including. While silicon photonics has enabled significant advancements, it faces inherent challenges, including bandwidth limitations and susceptibility to noise. We'll explore what optical modulation is, how it works, the different types of modulation (including advanced formats), and why optical isolators are vital to keeping those light signals clean. Due to the ability of optical modulators to achieve rapid modulation of optical signals, meeting the demands of high-speed data transmission, modulators based on different novel nanomaterials have become one of the research hotspots over the past decade.
