

Overcurrent relay protection return current

Overview

Construction and working principle of instantaneous over current relay is quite simple. In an instantaneous overcurrent relay, a magnetic core is wrapped with a current coil. An iron piece, supported by a hinge and a restraining spring, is positioned such that it remains detached from the core when current is below a preset threshold, keeping the relay in the closed position. This relay is created by applying intentional time delay after crossing pick up the value of the current. A definite time overcurrent relay can be adjusted to issue a trip output at an exact amount of time after it picks up. Thus, it has a time setting adjustment and pickup adjustment. Inverse time overcurrent relays, typically found in induction type rotating devices, operate faster with increased input current, inversely varying their operation time with current. This characteristic is ideal for swift fault clearing in severe conditions. Additionally, this inverse timing can also be programmed into microprocessor-based relays. In an overcurrent relay, achieving perfect inverse time characteristics is challenging. As system current rises, so does the secondary current from the current transformer (CT) until the CT saturates, halting further increases in relay current. This saturation marks the limit of inverse characteristic effectiveness, leading to a fixed minimum operation time.
