

Working principle of photovoltaic plastic-encapsulated modules

Overview

The scientists explained that in the proposed laminate-free, plastic-encapsulated solar module design, PC sheets replace glass, while a pressure- and heat-based process with a 3D-printed PC seal encapsulates the module and holds the cells in place without EVA. Photovoltaic (PV) technology enables the conversion of solar energy into electricity. Si-based PV modules, which currently represent more than 90% of the global PV market, are expected to be in high demand in the future. Image: University of Western Ontario, Journal of Cleaner. Appropriate encapsulation schemes are essential in protecting the active components of the photovoltaic (PV) module against weathering and to ensure long term reliability. For crystalline cells, poly(ethylene-co-vinyl acetate) (EVA) is the most commonly used PV encapsulant. For this purpose, the cells are encapsulated in a transparent. This paper presents an overview of the different materials currently on the market, the general requirements of PV module encapsulation materials, and the interactions of these materials with other module components. The main goal of Crystalline silicon.
